

REMOTE SENSING

DAVID ORME

OVERVIEW

1. Remote sensing concepts
2. Resolution:
 - Spectral
 - Spatial
 - Temporal
3. Earth observation products

MAPPING LANDSCAPES MANUALLY

Pros

- Very fine level of detail

Cons

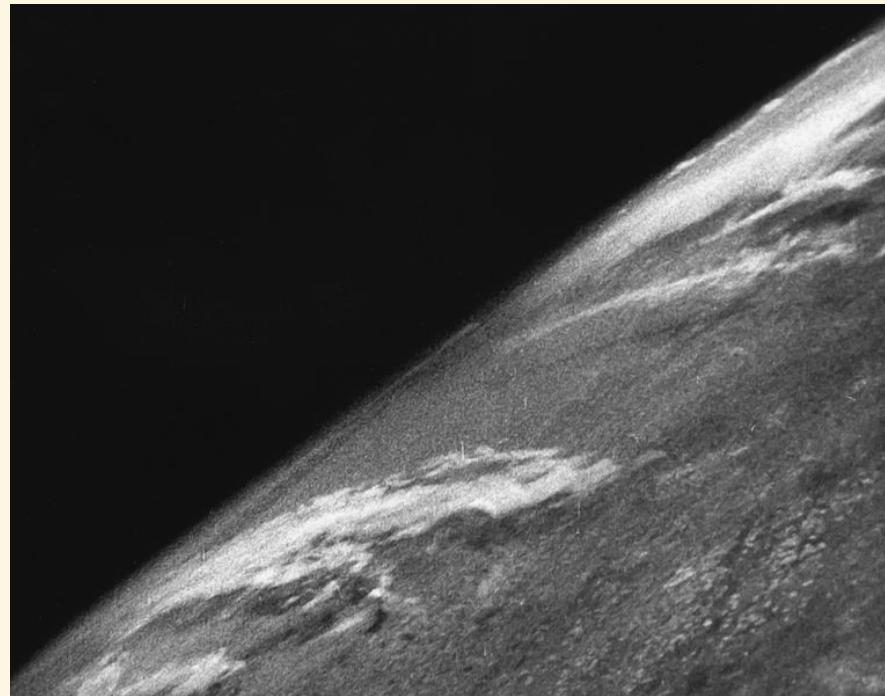

- Expensive
- Slow
- Inconsistency between locations and sampling periods

MAPS FROM IMAGES

Aerial photography
(1900s)

Satellite imagery
(1950s)

REMOTE SENSING

Remote sensors can be:

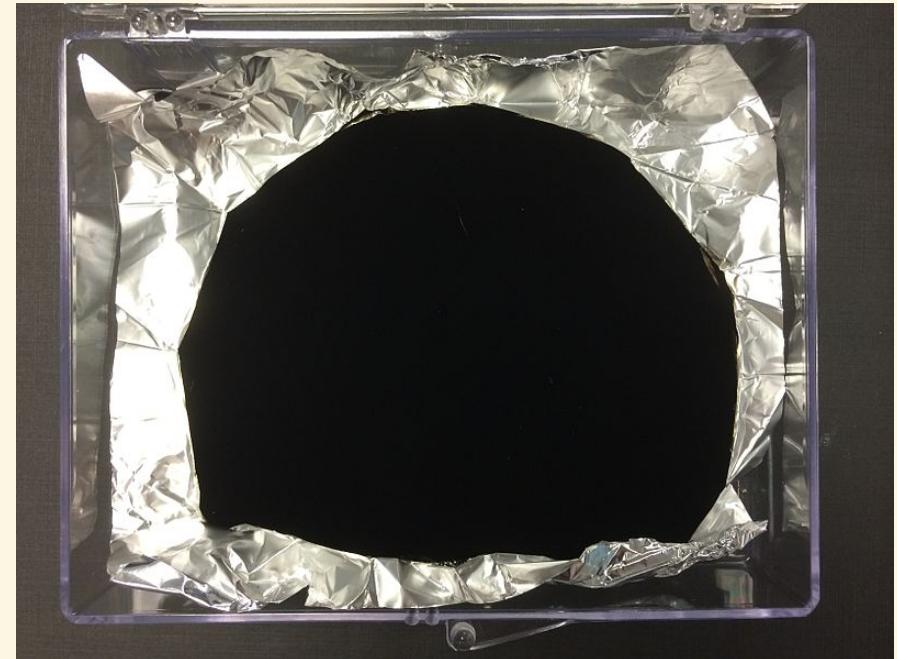

Passive: sense reflected solar radiation

Active: emit and sense reflected

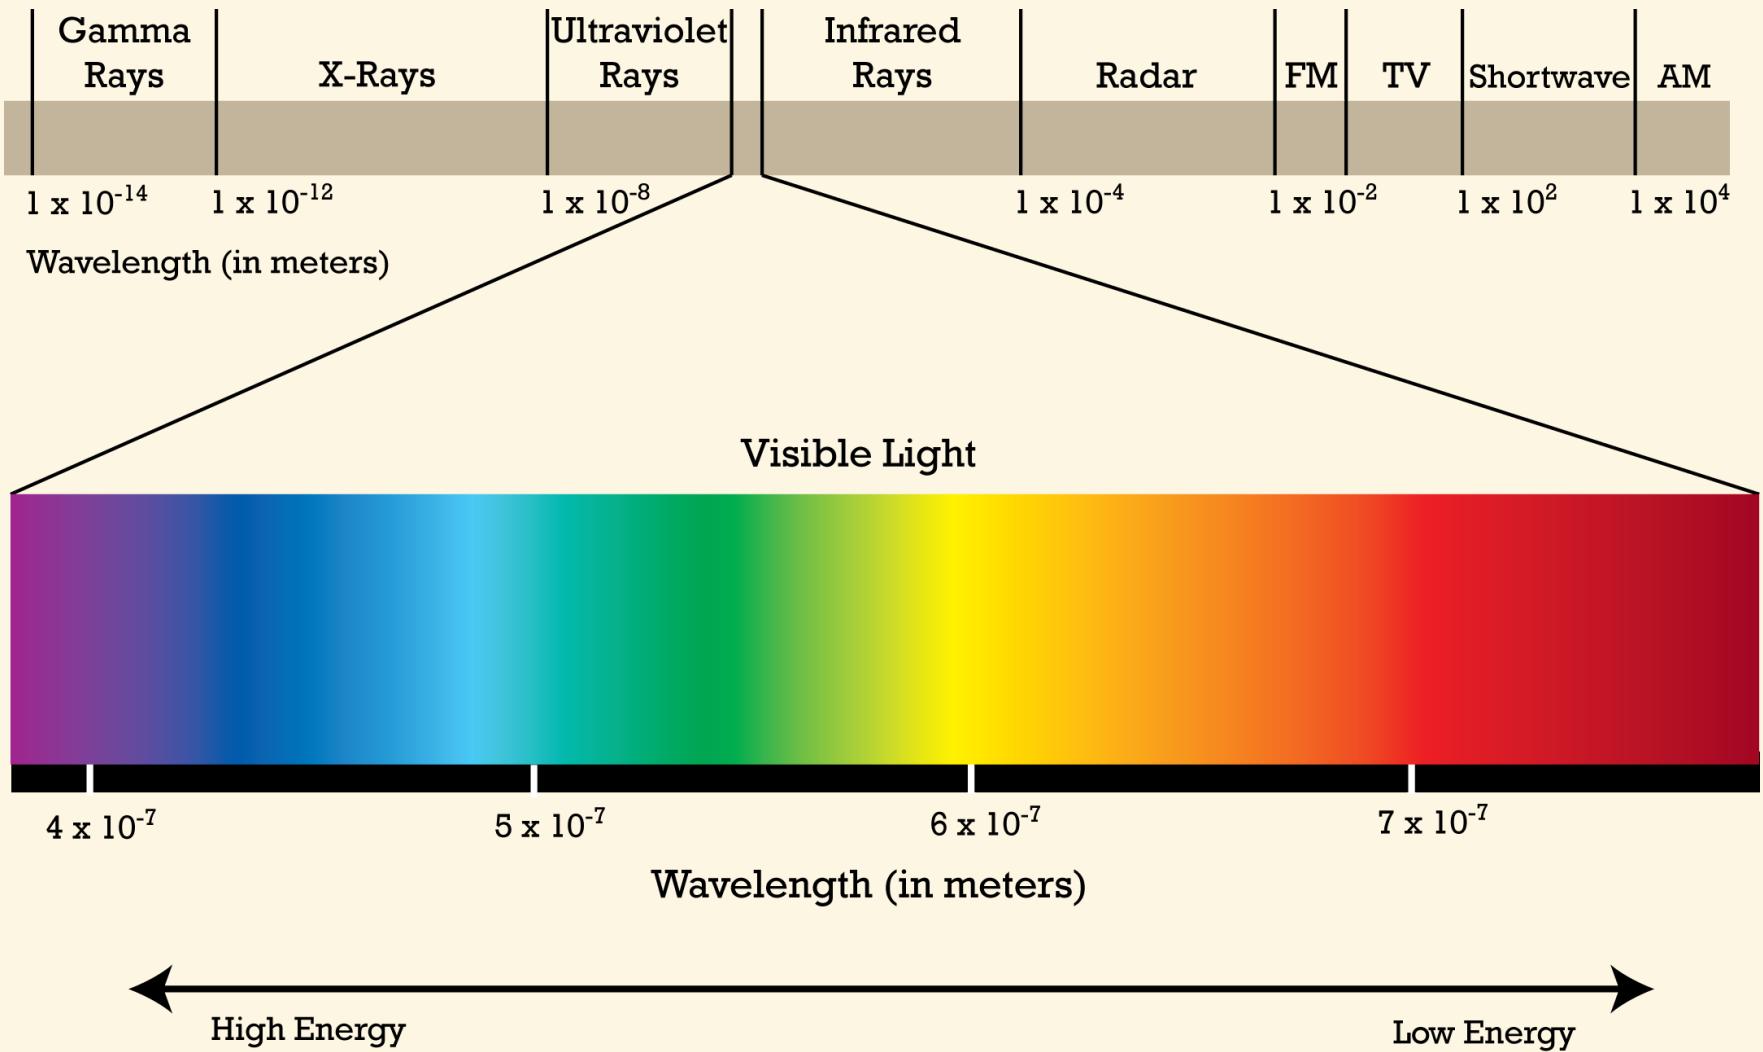

- LIDAR (light)
- RADAR (microwaves)
- Alteration in reflected light
- Trip time gives heights

REFLECTANCE

Albedo: the proportion of radiation reflected from a surface, strongly affected by texture and angle of incidence.

ELECTROMAGNETIC SPECTRUM

REFLECTANCE

Monochrome images

- Different objects have different albedo
- Construct maps by looking at contrast, texture and edges

REFLECTANCE

Multispectral images

- Albedo of surfaces vary with wavelength
- Compare bands recording reflectance in different wavelengths

REFLECTANCE

SATELLITE ORBITS

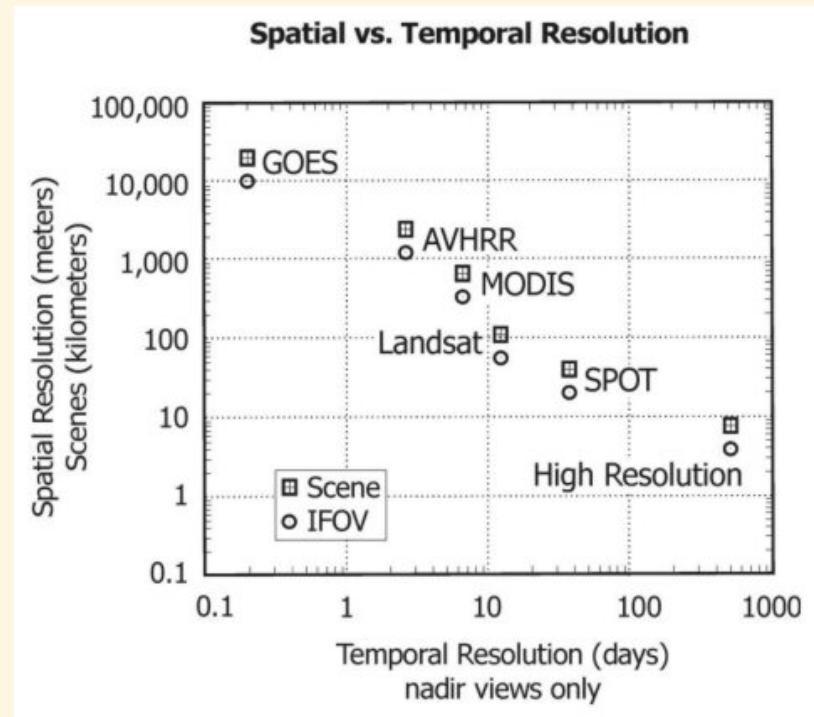

- **High earth**
geostationary orbits
(weather satellites),
- **Mid earth orbits**
(navigation and
communications)
- **Low earth orbits**
(earth observation)
- **Sun synchronous orbit**
(same time of day)

SPATIOTEMPORAL RESOLUTION

Low earth orbits:

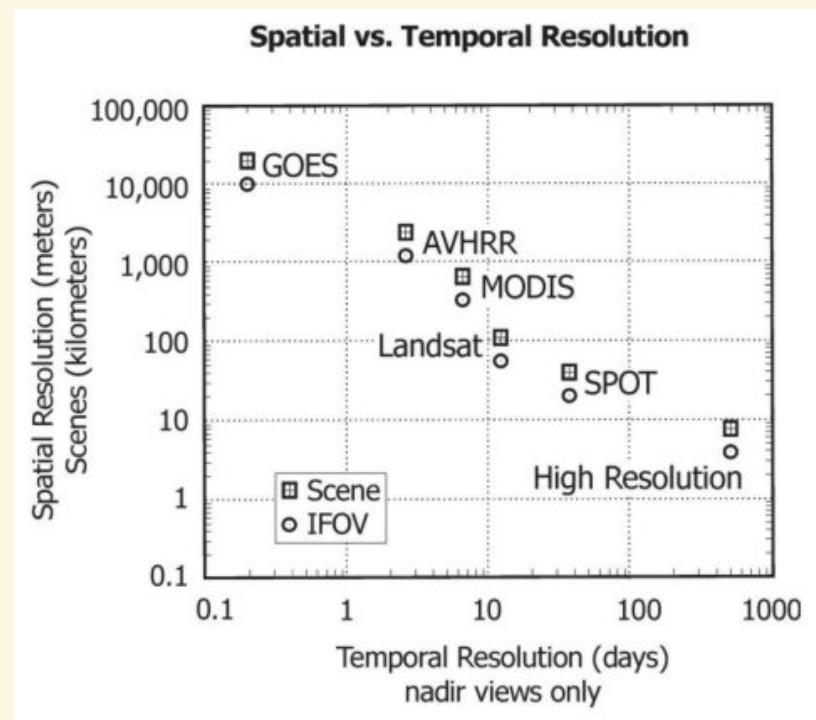

- Close to the planet
- High spatial resolution
- Narrow path widths
- Small scenes
- Less frequent images
- Use **constellations** of satellites

SPATIOTEMPORAL RESOLUTION

High earth orbits:

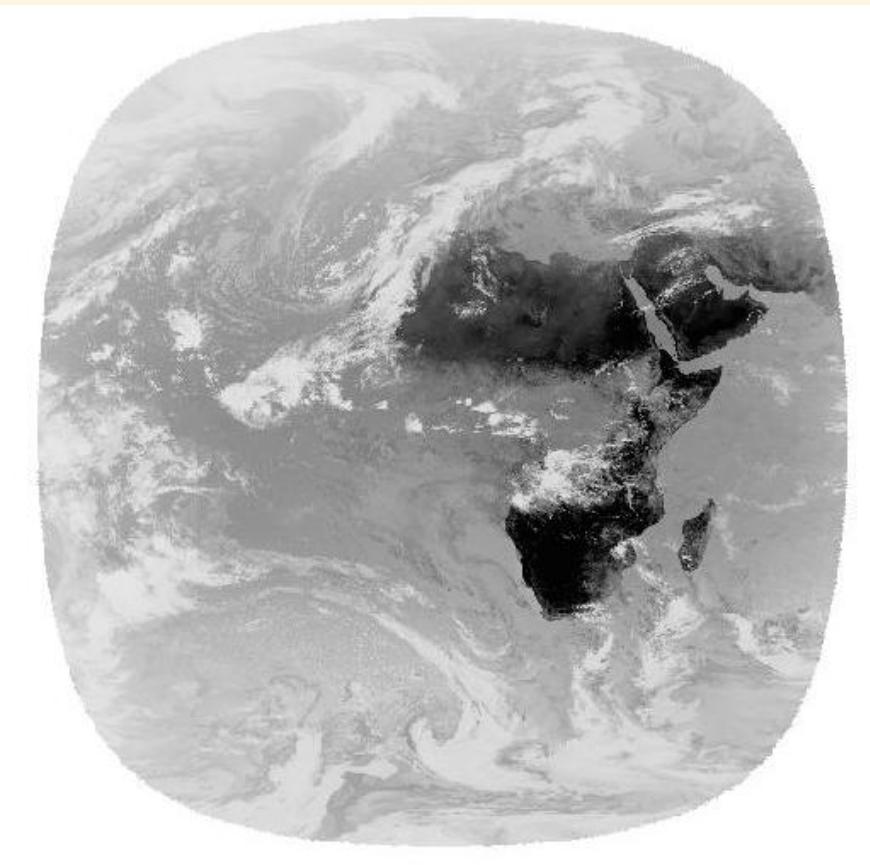

- Far out in space
- Low spatial resolution
- No path width
- Global scenes
- Can take images constantly

SPATIOTEMPORAL RESOLUTION

To put it another way:

Meteosat

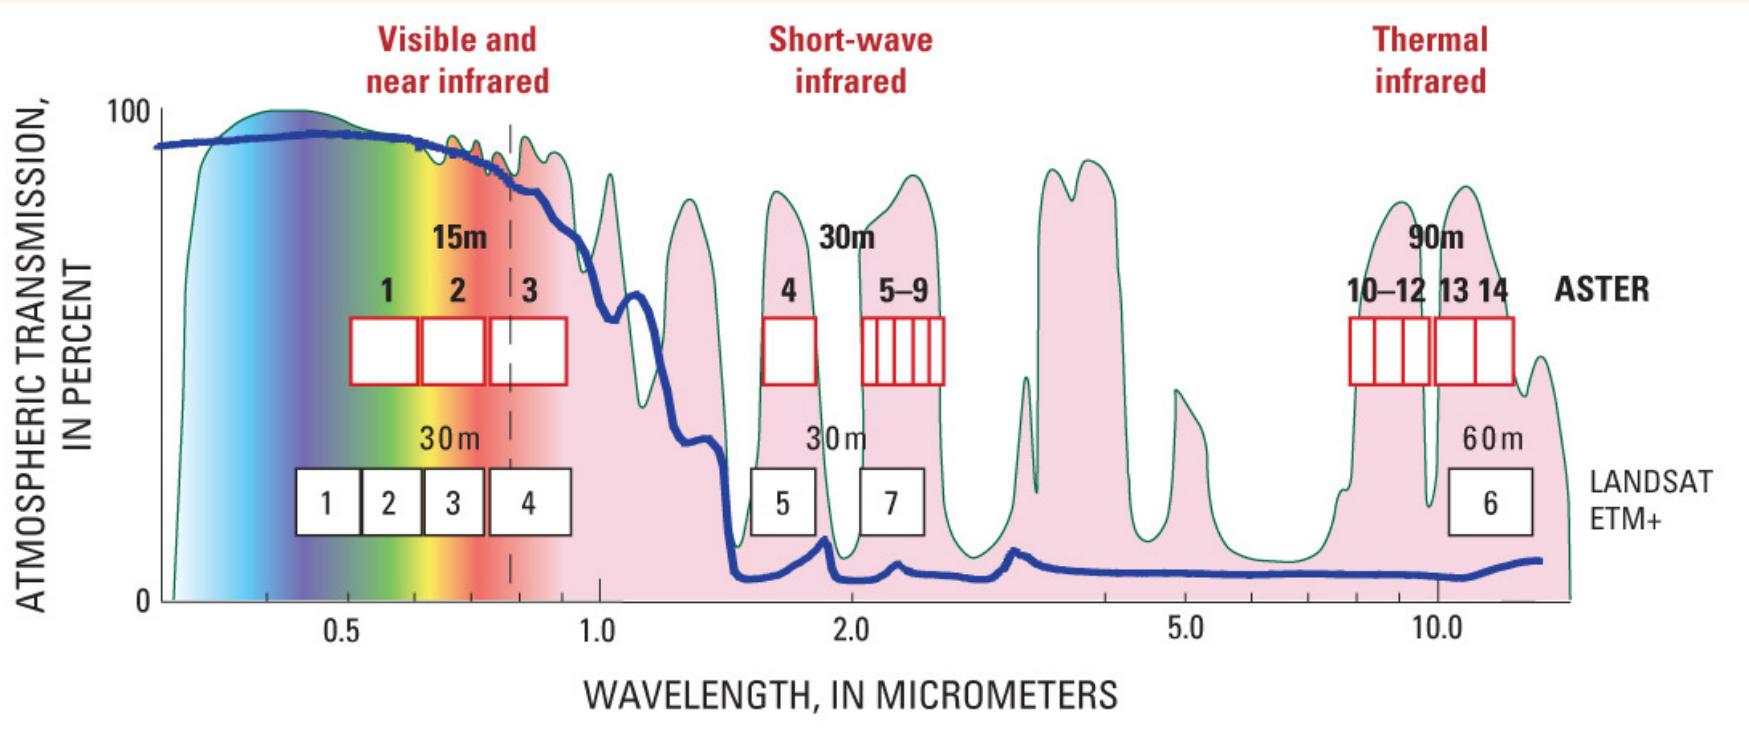

Pleiades

SPECTRAL RESOLUTION

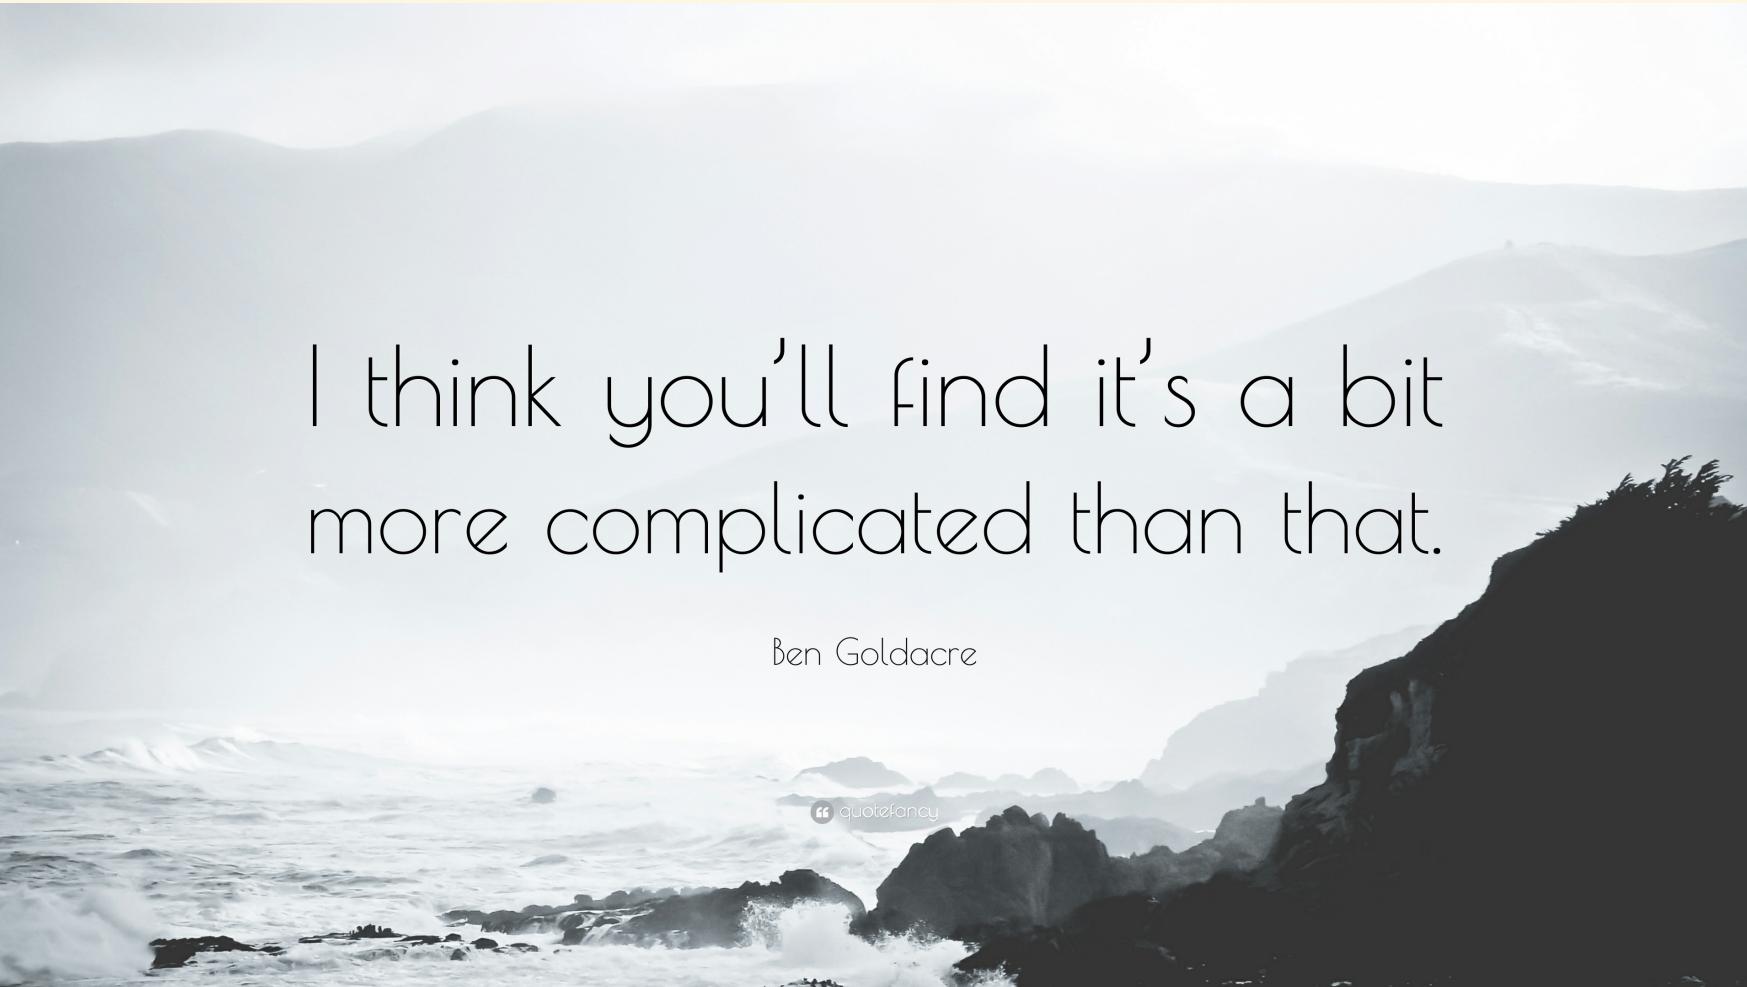

- Determined by the satellite mission
- Constrained by absorption of radiation by the atmosphere
- Light gathering sets resolution and band width

EXAMPLE PLATFORMS

Satellite	N	Bands	Revisit	Resolution (m)
Pleiades	2	5	1	2 / 0.5
Rapid Eye	5	5	1	5
Spot 7	1	5	2-3	6 / 1.5
ASTER	1	14	16	90 / 30 / 15
Landsat 8	1	11	16	100 / 30 / 15
MODIS Terra	1	36	1 - 2	1000 / 500 / 250

USING SATELLITE IMAGES

I think you'll find it's a bit
more complicated than that.

Ben Goldacre

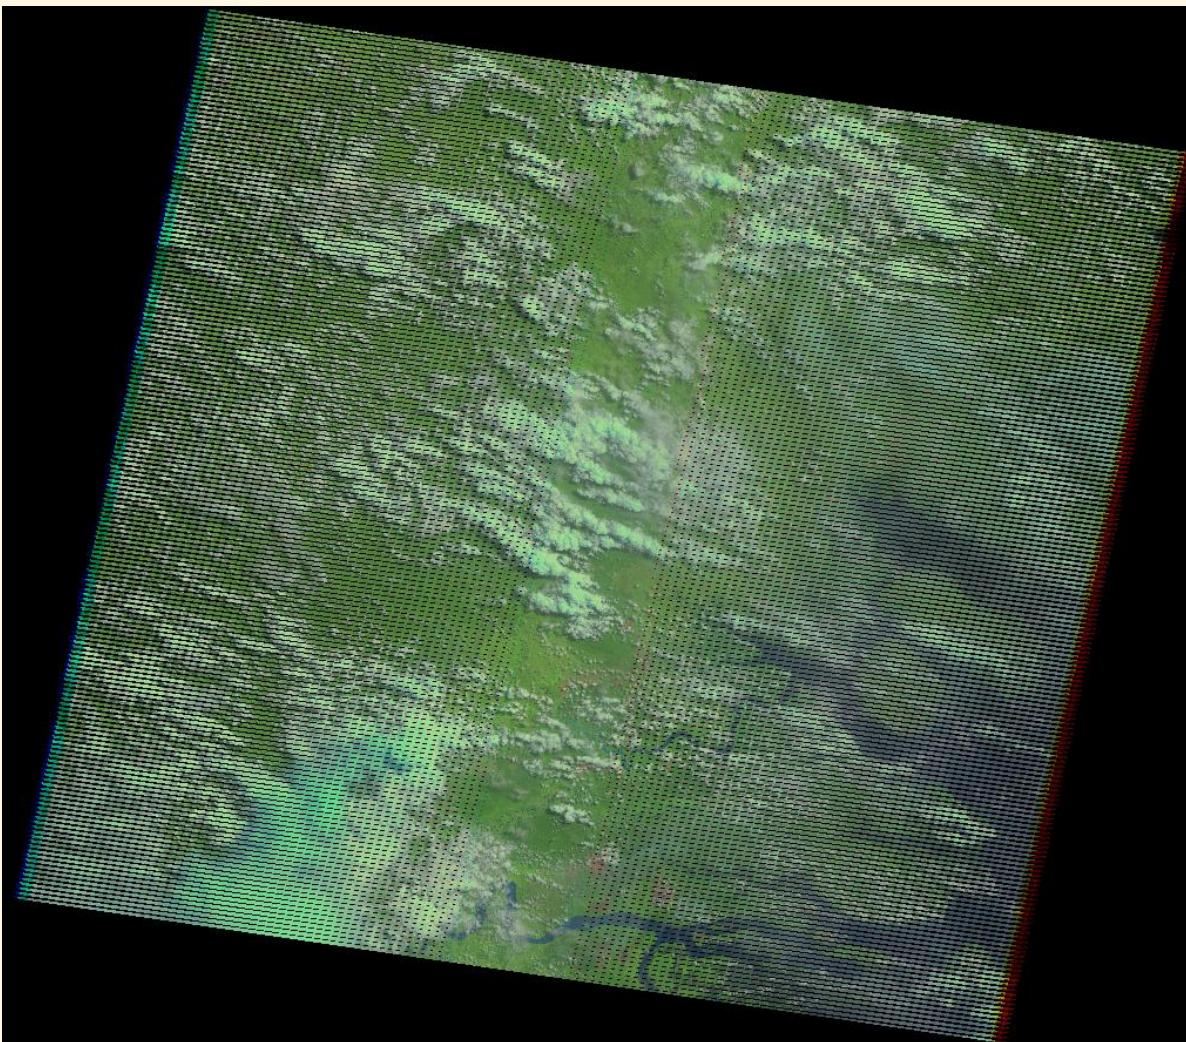

“ quotefancy

USING SATELLITE IMAGES

Multiple steps may be needed to use data:

- **Georeferencing:** where is the image?
- **Orthorectification:** remove perspective and terrain effects
- **Calibration:** convert the sensor value (an integer) to an actual reflectance value
- **Atmospheric correction:** aerosols and water vapour can all impose spectral biases on reflected light and vary on a daily basis.

USING SATELLITE IMAGES

EARTH OBSERVATION PRODUCTS

Use satellite reflectance data to produce derived maps

- Use standardised algorithms
- Map land surface traits at global scale
- Temporal scales: daily to annual
- Resolution: 250 m to > 8 km spatial resolution
- Validation: many have pixel by pixel 'accuracy'

Four examples of increasing complexity

VEGETATION INDICES

Simple direct calculation from sensor values:

- Normalized Difference Vegetation Index:

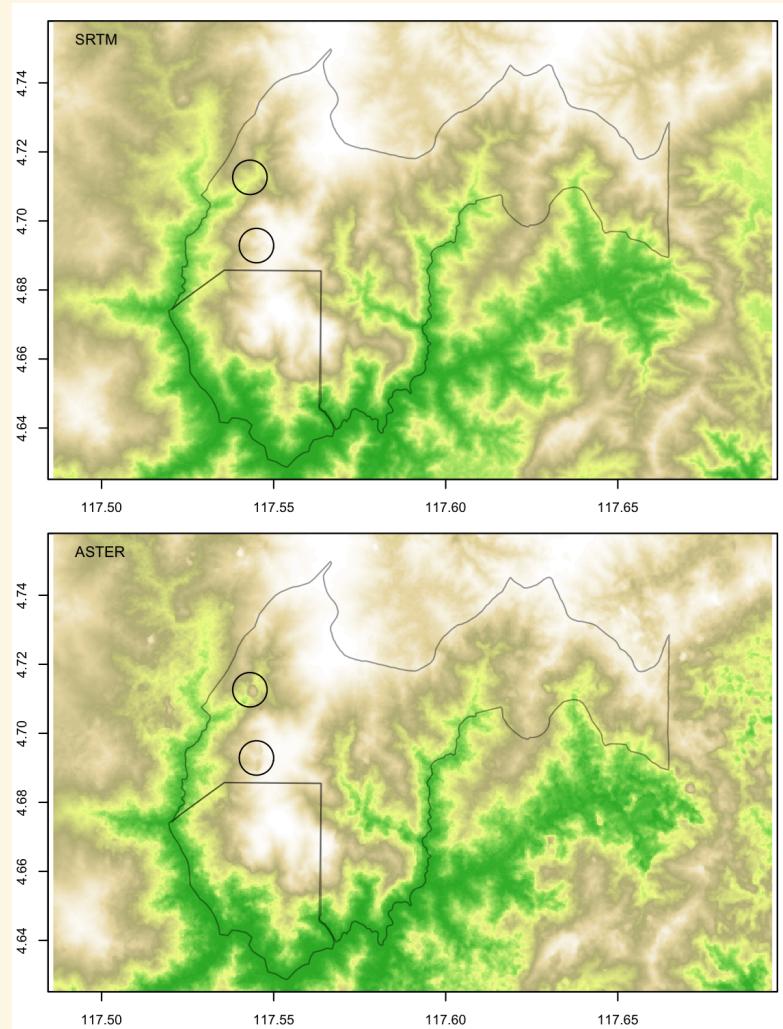

$$\text{NDVI} = \frac{(\text{NIR} - \text{RED})}{(\text{NIR} + \text{RED})}$$

- Enhanced Vegetation Index:

$$\text{EVI} = G \cdot \frac{(\text{NIR} - \text{RED})}{(\text{NIR} + C_1 \cdot \text{RED} - C_2 \cdot \text{Blue} + L)}$$

DIGITAL ELEVATION MODELS

- Shuttle Radar Topography Mission (SRTM)
- ASTER Terra DEM (stereoscopy)
- Both near global with 30 metre resolution

FIRE SIGNATURES

Live fires:

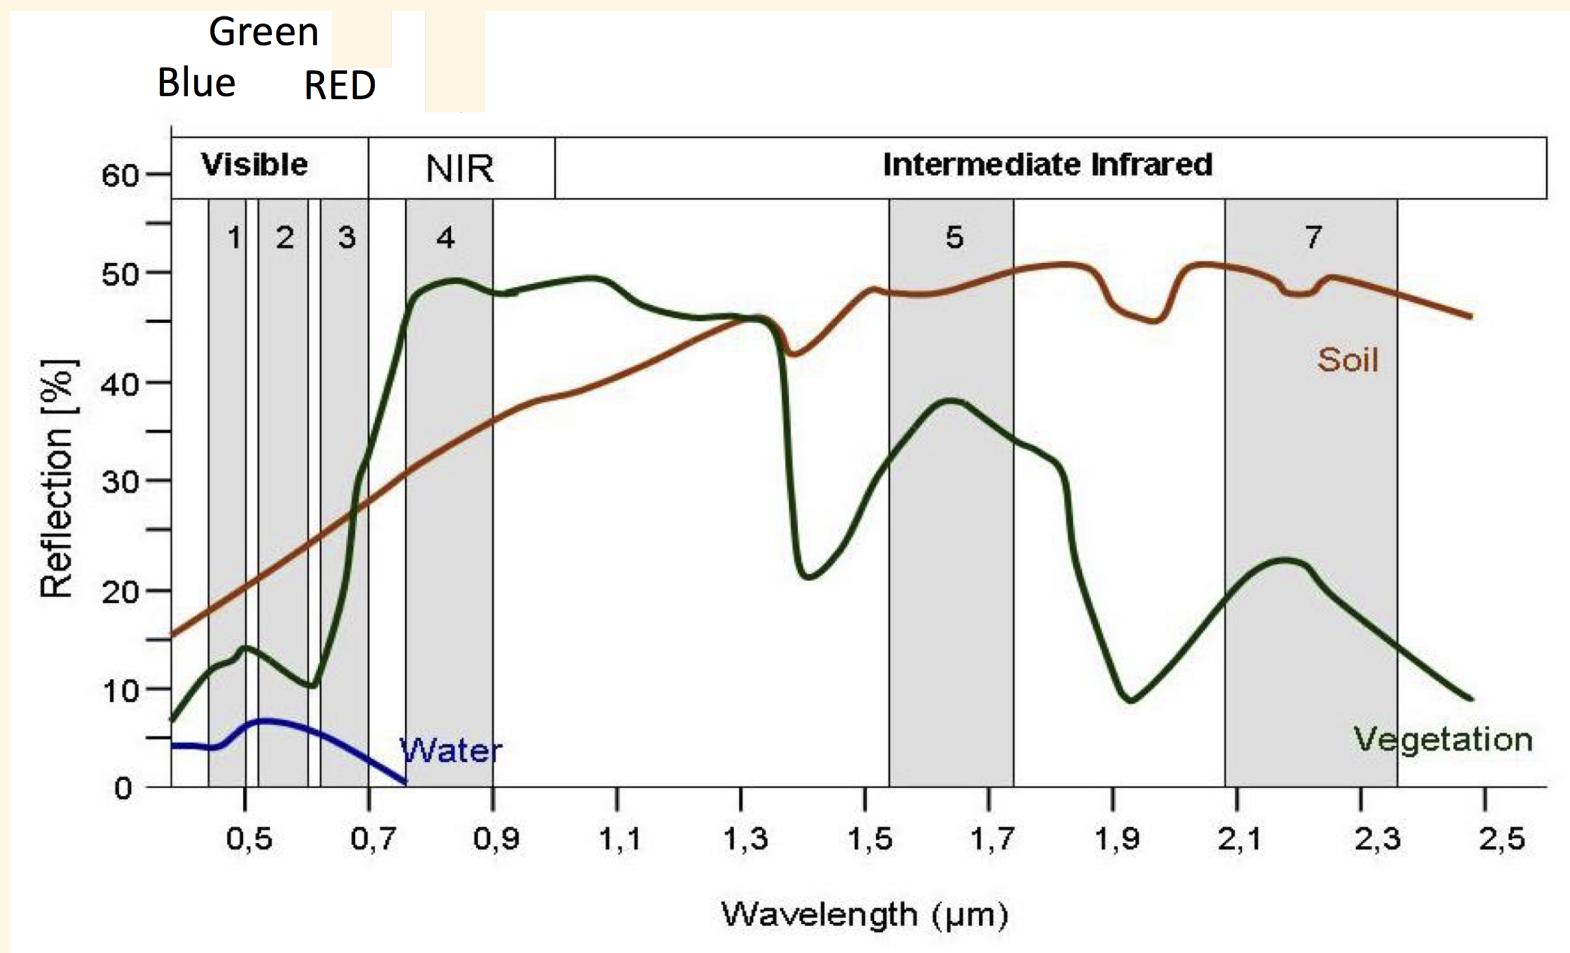

- Spectral signature in Infrared bands
- <http://fires.globalforestwatch.org/map>
- MODIS daily and 8 day fire observations at 1km resolution
- SPOT: annual fire frequencies (2000 - 2007)

Burned area:

- Change detection in successive images around fire pixels
- MODIS: monthly burned area in 500m pixels

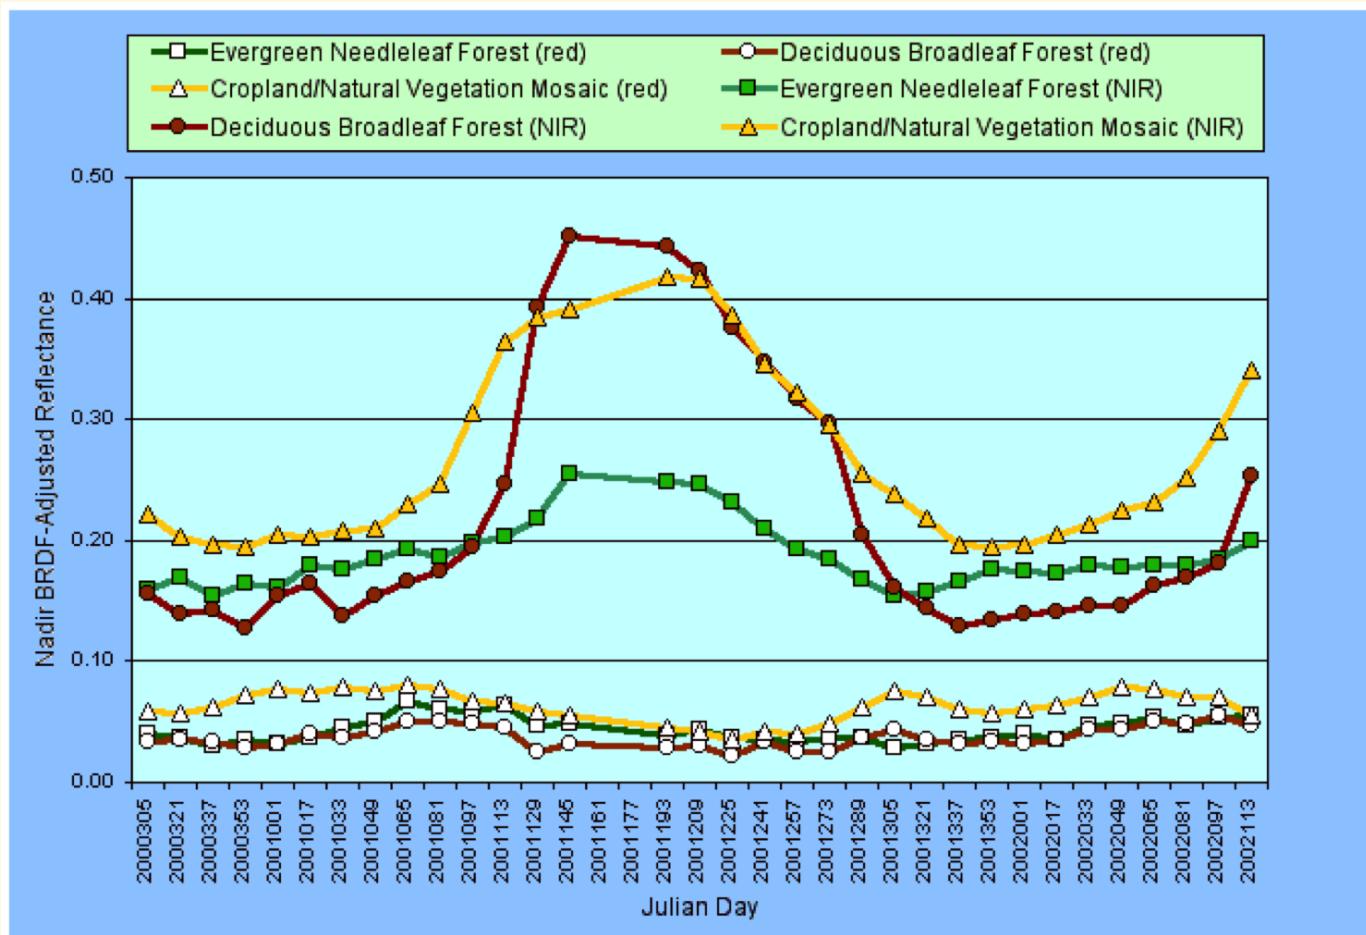

LAND COVER

Spectral signatures differ between different surfaces:

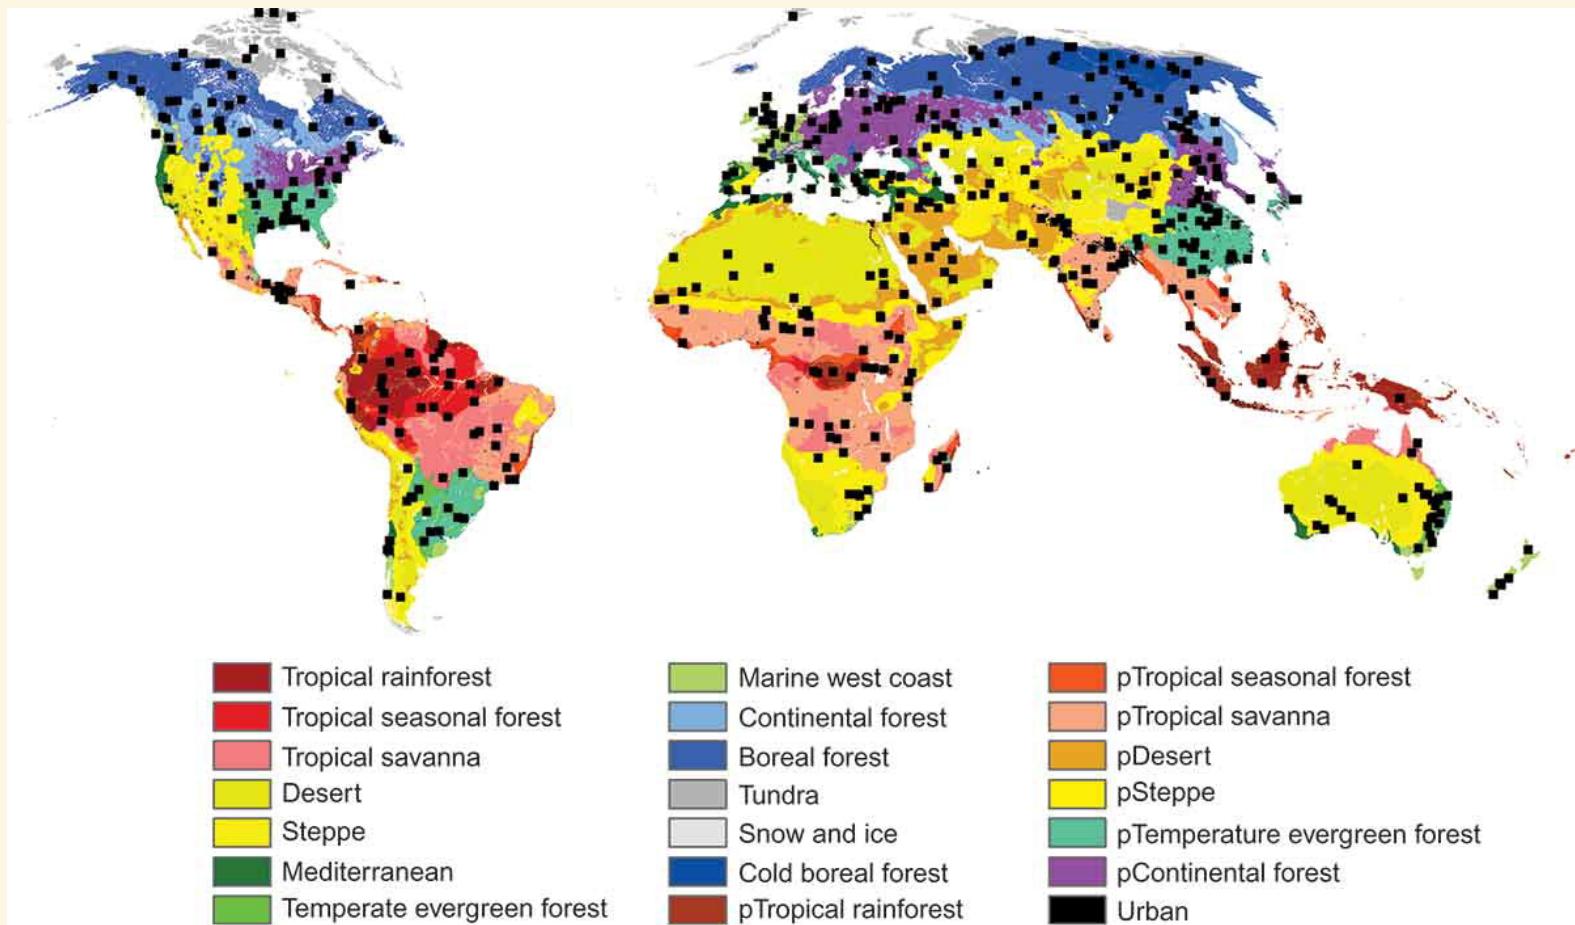

LAND COVER

Spectral signatures differ over time:

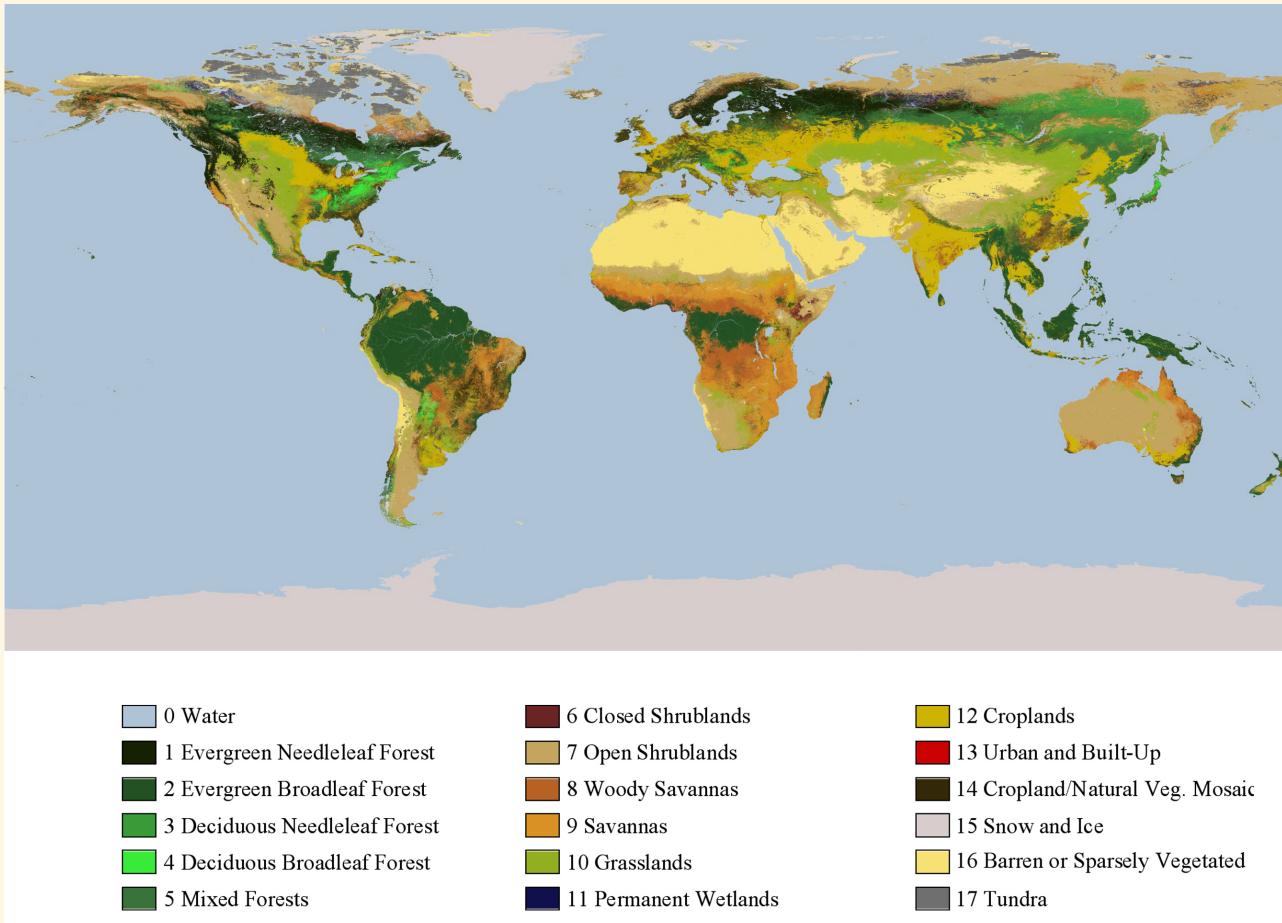

LAND COVER

Ground sampling ties spectral signatures to habitats

LAND COVER

Profiles can then be used to **classify** pixels to habitats

LAND COVER

Examples:

- MODIS: Annual summaries at 500 metre resolution using five different classification schemes
- <http://landcover.org/data/>
- Global Forest Change

PRODUCTIVITY

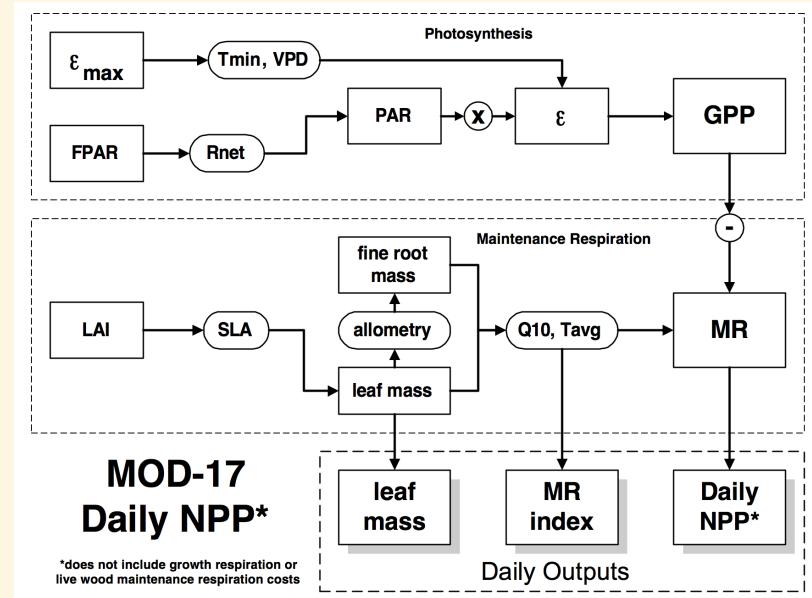

Plants use light to store carbon. If we know:

- The amount of **photosynthetically active light** absorbed
- The **radiation conversion efficiency**, given
 - the temperature and
 - humidity.
- Respiration costs.

Then we can predict gross and net primary productivity.

PRODUCTIVITY

- Remotely sensed reflected light
- Ground measured incident light
- Biome based models for:
 - conversion efficiency
 - respiration
